- ① *Problem definition*
- ② *Background*
- ③ *Transformation approach*
- ④ *Abstraction approach*
- ⑤ *Conclusions*

1. Introduction

Problem definition

Systems may be represented at different **levels of abstraction** (LoA).

Thermodynamics example:

Low-level / Base model:

Microscopic description $\mathbf{p}, \dot{\mathbf{p}}$.

High-level / Abstracted model:

Macroscopic description P, T, V .

LoA may be inaccessible, so we may want to *shift* among LoAs.

- We need a *mapping* between LoAs.
- We want the mapping to be *consistent*.
 - Ideally consistency is not only *observational*, but *interventional* too.

Problem definition

SCMs are becoming more popular for encoding causal models.

Lung cancer scenario example:

- How do we find a *mapping*?
- How do we define and guarantee some form of *consistency*?

This could allow us to shift between LoAs of SCMs, taking advantage of data and computational resources.

2. Background

SCMs

We express a causal model as a **structural causal model** \mathcal{M} [5, 6]:

- \mathcal{X} : set of *endogenous nodes* (S, T, C) representing variables of interest
- \mathcal{E} : Set of *exogenous nodes* (U_S, U_T, U_C) representing stochastic factors
- \mathcal{F} : Set of *structural functions* (f_S, f_T, f_C) describing the dynamics of each variable
- \mathcal{P} : Set of *distributions* (P_S, P_T, P_C) describing the random factors

Every SCM \mathcal{M} implies a (joint) **distribution** $P_{\mathcal{M}}$: $P_{\mathcal{M}}(S, T, C)$

Interventions

We can perform **interventions** on a causal model [5, 6]:

$do(T = 1)$

- 1 Remove incoming edges in the intervened node
- 2 Set the value of the intervened node

An intervention ι_1 effectively defines a new **intervened model** \mathcal{M}_{ι_1} such that $P_{\mathcal{M}}(S, T, C) \neq P_{\mathcal{M}_{\iota_1}}(S, T, C)$

Consistency

- **Observational consistency:** sampling the two models I obtain the same (observational) distributions of interest.

$$P_{\mathcal{M}}(S, C) = P_{\mathcal{M}'}(S', C')$$

- **Interventional consistency:** under an intervention the two models produce the same (interventional) distributions of interest.

$$P_{\mathcal{M}}(C|do(S = 0)) = P_{\mathcal{M}'}(C'|do(S' = 0))$$

Two approaches

Lung cancer scenario example:

$$\mathcal{M}'[S'] = \mathcal{M}'[C'] = \{0, 1\}$$

$$\mathcal{M}[S] = \mathcal{M}[T] = \mathcal{M}[C] = \{0, 1\}$$

- The **transformation** approach [9]
- The **abstraction** approach [8]

3. Transformation approach [9]

The *transformation* approach: transformation

Given two SCMs \mathcal{M} and \mathcal{M}' , let us consider the **transformation**:

$$\tau : \prod_i \mathcal{M}[X_i] \rightarrow \prod_j \mathcal{M}'[X_j]$$

τ : domain of the variables of $\mathcal{M} \rightarrow$ domain of the variables of \mathcal{M}' .

τ : an output/configuration of $\mathcal{M} \mapsto$ an output/configuration of \mathcal{M}' .

This implies a (pushforwarded) distribution on \mathcal{M}' :

$$\begin{array}{ccc} \prod_i \mathcal{M}[X_i] & \xrightarrow{\tau} & \prod_j \mathcal{M}'[X_j] \\ \vdots & & \vdots \\ P_{\mathcal{M}} & \xrightarrow{\tau} & P_{\mathcal{M}'} \\ & & \tau(P_{\mathcal{M}}) \end{array}$$

If $\tau(P_{\mathcal{M}}) = P_{\mathcal{M}'}$ we have *observational consistency*.

The *transformation* approach: an example (I)

Lung cancer scenario example:

$$\tau : \mathcal{M}[S] \times \mathcal{M}[T] \times \mathcal{M}[C] \rightarrow \mathcal{M}'[S'] \times \mathcal{M}'[C']$$

$$\tau : \{0, 1\}^3 \rightarrow \{0, 1\}^2$$

$$\tau : (s, t, c) \mapsto (s, c)$$

$$\tau : (0, 1, 1) \mapsto (0, 1)$$

Observational consistency condition:

$$\begin{array}{ccc} \{0, 1\}^3 & \xrightarrow{\tau} & \{0, 1\}^2 \\ \vdots & & \vdots \\ P_{\mathcal{M}} & \xrightarrow{\tau} & \tau(P_{\mathcal{M}}) = P_{\mathcal{M}'} \end{array}$$

The *transformation* approach: poset of interventions

Let us now consider a set of interventions of interest \mathcal{I} on \mathcal{M} .

The set of interventions has a *partially ordered set* structure wrt inclusion.

The *transformation* approach: poset of interventions

The poset of interventions induces a *partially ordered set* structure over SCMs.

The *transformation* approach: exact transformation

Let us consider a mapping between interventions:

$$\omega : \mathcal{I} \rightarrow \mathcal{I}'$$

ω : an intervention on $\mathcal{M} \mapsto$ an intervention on \mathcal{M}' .

A transformation is an *exact transformation* if there exist a surjective order-preserving ω such that:

$$\begin{array}{ccc}
 P_{\mathcal{M}} & \xrightarrow{\tau} & \tau(P_{\mathcal{M}}) = P_{\mathcal{M}'} \\
 \downarrow \iota & & \downarrow \omega(\iota) \\
 P_{\mathcal{M}_\iota} & \xrightarrow{\tau} & \tau(P_{\mathcal{M}_\iota}) = P_{\mathcal{M}'_{\omega(\iota)}}
 \end{array}$$

where $\tau(P_{\mathcal{M}_\iota}) = P_{\mathcal{M}'_{\omega(\iota)}}$ for every $\iota \in \mathcal{I}$.

The *transformation* approach: consistency

(*Interventional*) consistency is the commutativity of the diagram:

$$\begin{array}{ccc}
 P_{\mathcal{M}} & \xrightarrow{\tau} & \tau(P_{\mathcal{M}}) = P_{\mathcal{M}'} \\
 \downarrow \iota & & \downarrow \omega(\iota) \\
 P_{\mathcal{M}_\iota} & \xrightarrow{\tau} & \tau(P_{\mathcal{M}_\iota}) = P_{\mathcal{M}_{\omega(\iota)}}
 \end{array}$$

It produces the same result to:

- abstract, then intervene ($\omega(\iota) \circ \tau$)
- intervene, then abstract ($\tau \circ \iota$)

The *transformation* approach: an example (II)

Lung cancer scenario example:

$$\tau : (s, t, c) \mapsto (s, c)$$

Set of interventions: $\mathcal{I} = \{\emptyset, do(S = 0)\}$

$$\omega : \begin{cases} \emptyset \mapsto \emptyset \\ do(S = 0) \mapsto do(S' = 0) \end{cases}$$

Consistency condition:

$$\begin{array}{ccc} P_{\mathcal{M}}(S, T, C) & \xrightarrow{\tau} & P_{\mathcal{M}'}(S', C') \\ \downarrow \iota & & \downarrow \omega(\iota) \\ P_{\mathcal{M}}(T, C | do(S = 0)) & \not\approx & P_{\mathcal{M}'}(C' | do(S' = 0)) \end{array}$$

The *transformation* approach: summary

Given:

- A low-level model \mathcal{M} with a set of interventions of interest \mathcal{I} ;
- A high-level model \mathcal{M}' ;
- A surjective order-preserving $\omega : \mathcal{I} \rightarrow \mathcal{I}'$

an **exact transformation** τ guarantees that if I:

- work (intervene) at low-level and then switch (abstract) to high-level,
- or, switch first to high-level and then work there,

I will observe the same statistical behavior in the two models.

The *transformation* approach: a few observations

- A *coarse-grained* description of abstraction.
- *Structural information* mediated only through interventions.
- Consistency wrt to a limited *set of interventions*.
- Work with *continuous models*.

4. Abstraction approach [8]

The *abstraction* approach: abstraction

Let \mathcal{M} and \mathcal{M}' be two finite SCMs with finite domains. An **abstraction** is a tuple

$$(R, a, \alpha)$$

where

- $R \subseteq \mathcal{X}_{\mathcal{M}}$ is a subset of *relevant nodes* among the endogenous nodes of \mathcal{M} .
- $a : R \rightarrow \mathcal{X}_{\mathcal{M}'}$ is a *surjective function* mapping a low-level node in \mathcal{M} to a high-level node in \mathcal{M}' .
- α is a *collection of surjective functions*, one for each high-level node X' , defined as $\alpha_{X'} : \mathcal{M}[a^{-1}(X')] \rightarrow \mathcal{M}'[X']$.
 $\alpha_{X'}$ maps an output of the low-level nodes sent onto X' by a onto an output of X' .

The *abstraction* approach: an example (I)

Lung cancer scenario example:

$$R = \{S, C\} \subseteq \mathcal{X}_{\mathcal{M}}$$

$$a : R \rightarrow \mathcal{X}_{\mathcal{M}'}$$

$$a : \begin{cases} S \mapsto S' \\ C \mapsto C' \end{cases}$$

$$\alpha : \begin{cases} \alpha_{S'} : \{0, 1\} \rightarrow \{0, 1\} \\ \alpha_S : s \mapsto s \\ \alpha_{C'} : \{0, 1\} \rightarrow \{0, 1\} \\ \alpha_C : c \mapsto c \end{cases}$$

The *abstraction* approach: consistency

We have (*interventional consistency*) if the following diagram commutes for all the disjoint subsets $X', Y' \in \mathcal{X}_{\mathcal{M}'}$ for every value in $\mathcal{M}[a^{-1}(X')]$:

$$\begin{array}{ccc}
 \mathcal{M}[a^{-1}(X')] & \xrightarrow{\mathcal{M}[\phi_{a^{-1}(Y')}] } & \mathcal{M}[a^{-1}(Y')] \\
 \alpha_{X'} \downarrow & & \downarrow \alpha_{Y'} \\
 \mathcal{M}'[X'] & \xrightarrow{\mathcal{M}'[\phi_{Y'}]} & \mathcal{M}'[Y']
 \end{array}$$

It produces the same result to:

- mechanism, then abstract ($\alpha_{Y'} \circ \mathcal{M}[\phi_{a^{-1}(Y')}]$)
- abstract, then mechanism ($\mathcal{M}'[\phi_{Y'}] \circ \alpha_{X'}$)

The *abstraction* approach: an example (II)

Lung cancer scenario example:

Disjoint subsets in
 $\mathcal{X}_{\mathcal{M}'} = \{\{S'\}, \{C'\}\}$

Consistency condition:

The *abstraction* approach: abstraction error

If the diagram does not commute for $X', Y' \in \mathcal{X}_{\mathcal{M}'}$:

$$\begin{array}{ccc}
 \mathcal{M}[a^{-1}(X')] & \xrightarrow{\mathcal{M}[\phi_{a^{-1}(Y')}] } & \mathcal{M}[a^{-1}(Y')] \\
 \alpha_{X'} \downarrow & & \downarrow \alpha_{Y'} \\
 \mathcal{M}'[X'] & \xrightarrow{\mathcal{M}'[\phi_{Y'}]} & \mathcal{M}'[Y']
 \end{array}$$

I can compute the *abstraction error* for X', Y' :

$$E_{\alpha}(X', Y') = D_{\text{JSD}}(\alpha_{Y'} \circ \mathcal{M}[\phi_{a^{-1}(Y')}], \mathcal{M}'[\phi_{Y'}] \circ \alpha_{X'})$$

I can compute the *overall abstraction error* as the worst-case:

$$e(\alpha) = \sup_{X', Y' \in \mathcal{X}_{\mathcal{M}'}} E_{\alpha}(X', Y')$$

The *abstraction* approach: an example (II)

Lung cancer scenario example:

Assuming no commutativity

I can compute *abstraction error*:

$$E_{\alpha}(S', C') = D_{JSD}(\alpha_{C'} \circ \mathcal{M}[\phi_C], \mathcal{M}'[\phi_{C'}] \circ \alpha_{S'})$$

Since there are not other subsets this is also the *overall abstraction error*:

$$e_{\alpha} = E_{\alpha}(S', C')$$

The *abstraction* approach: summary

Given:

- A low-level model \mathcal{M} ;
- A high-level model \mathcal{M}' ;
- An abstraction (R, a, α)

a **zero-error abstraction** guarantees that, under intervention, if I:

- work (mechanism) at low-level and then switch (abstract) to high-level,
- or, switch first to high-level and then work there,

I will observe the same statistical behavior in the two models.

The *abstraction* approach: a few observations

- A *fine-grained* description of abstraction.
- *Structure* defines abstraction.
- Consistency wrt to *all interventions* (in a finite set).
- Work with *finite models*.
- Finiteness reduces SCMs to sets and stochastic matrices.
- Commuting diagram grounded in category theory.

5. Conclusions

Properties of abstraction

We discussed:

- Observational consistency
- Interventional consistency

We have not dealt with:

- Compositionality [9, 8, 7]
- Counterfactual consistency
- Locality
- Other formalizations [2, 1, 4]

Learning/discovery/search aspects

We discussed:

- Formal setup of abstraction
- Well-defined models
- Verification of properties of abstractions

We have not dealt with:

- Learning abstractions
 - Learning causal features [3]
- Transferring knowledge between models
 - Homogeneity of abstractions and interventions

Thanks!

Thank you for listening!
